UNIVERSITY OF ALBERTA

FACULTY OF GRADUATE STUDIES AND RESEARCH

The undersigned certify that they have read and recommend to the Faculty of Graduate Studies and Research for acceptance a thesis entitled "Performance And Impact Of An Alfalfa Processing Plant", submitted by Elijah Kagangri Busingye in partial fulfilment of the requirements for the degree of Master of Science.

.....
Supervisor

.....

.....

Date...21...April...1976

ABSTRACT

Alfalfa is recognized as a valuable protein crop. But the conventional harvest as hay is so bulky and subject to protein loss, that it has restricted market opportunity. Therefore, processing by dehydration and pelletising has recently been encouraged in the Province of Alberta.

This thesis attempts to examine the following: (1) the financial viability of the Smoky Lake Alfalfa Processing Plant, and (2) the competitive impact of alfalfa production in the county of Smoky Lake. Examination of financial viability is tied to the concepts of cash flow analysis, linear programming is used to study possible impacts on farm enterprises of alfalfa.

In this study, financial viability requires that the financial rate of return be more than the market rate of interest. The procedure involved cash flows projections of the Smoky Lake plant for a planning period of fifteen years. The computations yielded a return of 15.2 percent. Sensitivity analysis varying throughput as a percent of capacity and varying price provided a test for vulnerability of the earning capacity of the plant.

The competitive impact of alfalfa production, was estimated using a general Linear Programming Model for Northern Alberta augmented by several alfalfa production activities obtained from a sample survey of alfalfa growers in Smoky Lake County. Corresponding constraining equations for the County

were defined. A IBM mathematical programming system was used for manipulation of the problem toward a solution. The conclusion was reached that the production of alfalfa for processing purposes would not have a significant impact on the cropping and livestock patterns in Smoky Lake County.

ACKNOWLEDGEMENTS

The writer wishes to express appreciation to those who provided assistance in the preparation and completion of this study. Grateful recognition is extended to the Alberta Department of Agriculture and Canadian International Development Agency for financial support. There can be no doubt, however, that the chief debt is owed to Dr. L.P. Apedaile who supervised the research and kept prodding me to complete this thesis.

Appreciation is also due to Mr. Ronn Bence for technical assistance and Mr. A.Y. Bobe for the encouragement. Many thanks are due to the typist, Mrs. Helen Kuzyk who worked through several drafts of the manuscript and to Miss Evelyn Shapka for literary corrections.

Above all, I would like to thank my parents, sisters and my daughter for sacrificing so much.

CHAPTER I

Agricultural Processing Concepts

Alfalfa processing is an integral part of the policy of agriculture and rural development in Alberta. It is the intention of the Provincial Government to "maintain the family farm, stimulate rural growth, and increase job opportunities through expansionistic agriculture policies, including the development of agriculture secondary and tertiary industry."¹

The present concept of the processing of agricultural products is part of the technological change that has occurred in the agricultural sector over the post-war period. The agricultural sector has become dominated by more efficient, and expensive equipment. As a result, relatively less labour has been employed (nearly 1.2 million people were employed in agriculture in 1946, this had declined by 61 percent to 467,000 in 1973). The small number of people engaged in agriculture have to diversify their farming operations, hedge against risk and uncertainty, and operate with increased efficiency.

The processing of agricultural products reduces uncertainty adds value to resources, and through a multiplier effect, adds jobs and incomes to communities. Alfalfa processing is an example of this theory in action. The various industrial assis-

¹ Alberta Department of Agriculture, Analysis and Implications For the Development of The Alfalfa Processing Industry in Alberta, Agdex 121/843 (Edmonton: Alberta Agriculture, 1974), p. 1.

tance programs¹ available to alfalfa processors in Alberta are on the one hand, recognition of the confidence that Government has in this principle, and on the other, justification for evaluation of the performance of the industry.

Recent Expansion in Alfalfa Processing

Alfalfa is a crop commercially produced on a competitive basis in Alberta. The demand for this crop is increasing in both the domestic and international markets. However, to capture an extensive portion of this demand, there is a need to transform alfalfa from a bulky product to a more condensed form that is acceptable in market channels. This has been taking place recently through alfalfa processing, which reduces waste and creates a product which is cheaper to transport.

The alfalfa processing industry in the Province has achieved considerable growth in recent years. Since the end of 1973, when there were seven plants in operation, five new plants have been opened, bringing the total number to twelve at the end of 1975. The estimated production increased from 36,000 tons of dehydrated alfalfa in 1973 to 84,000 tons in 1975. Figure 1 shows the locations of the alfalfa processing plants in Alberta. With the exception of one plant at Vauxhall, which has been in operation for the last twelve years, the rest are less than seven years old.

¹ The incentive loan which is granted through the Alberta Opportunity Company is one of the various industrial assistance programs. The loan is approved for a period of five years without interest and application may be made for forgiveness after that time.

MAP OF ALBERTA SHOWING THE LOCATIONS OF ALFALFA
PROCESSING PLANTS, 1975

The recent expansion was encouraged by the formation of the Alberta Alfalfa Processors Cooperative Association. In its articles of incorporation, one of the objectives of the association is to "promote the economic welfare of alfalfa dehydrating and processing firms throughout the province, by acting as agents for the procuring of supplies and services, and promoting such research as may be deemed necessary."¹

Dehydrating plants in Alberta, depending on their locations, normally operate from June until the middle of October (about 120 days). Traditionally, the dehydrated alfalfa industry had consisted of small plants supplying local markets. Recently, the Economic Research and Analysis Branch, on behalf of the Department of Industry and Commerce, examined the possibility of expanding the dehydrating industry in Alberta by increasing the number and size of plants and developing export markets. It was hoped that the processing of alfalfa, being a relatively new activity in Alberta, would play an increasing role in the Alberta economy; hence, the justification for the expansion of the industry.

The Problem

One of the prime functions of alfalfa processing is to produce a diversified line of forage products. The products are to serve local, regional and foreign consumers. The Alberta

¹ Alberta Department of Agriculture, Analysis and Implications for the Development of The Alfalfa Processing Industry in Alberta, Agdex 121/843 (Edmonton: Alberta Agriculture, 1974), p. 1.

Department of Agriculture considers it important to investigate the competitive position of alfalfa relative to other crops in Alberta so that more informed decisions on production of dehydrated alfalfa can be made. The present study, which is based on the "Smoky Lake Alfalfa Processing Plant", forms part of the response to the investigation of the alfalfa industry.

The choice of the Smoky Lake Plant was at the discretion of the Alberta Department of Agriculture. The main reasons for the choice were that the plant is located in an important and high risk alfalfa growing area; the plant was experiencing several typical teething problems; and Smoky Lake Processors were among those who received the incentive loan through the Alberta Opportunity Company. The purpose of this study was to assess, from a financial and competitive impact perspective, the viability and the regional economic impact of the plant.

Therefore, the prime objectives of this thesis are:

- (1) To examine the financial viability of the Smoky Lake Alfalfa Processing Plant.
- (2) To examine the competitive impact of alfalfa production on the other farm enterprises.
- (3) To examine the regional impact of the plant as a market outlet for local resource based production.
- (4) To examine policy recommendations for the future of the plant.

CHAPTER II

ALFALFA INDUSTRY IN ALBERTA

Smoky Lake County

The town of Smoky Lake, the main center in the County of Smoky Lake, is 75 miles northeast of Edmonton on Highway 28. The alfalfa processing plant is located in the town. Figures 2 and 3 illustrate the main centres in Smoky Lake County and the location of the County, respectively.

Agriculture in Smoky Lake County is characterized by mixed farming and a broad base of salable commodities. According to the 1971 Census, there were 343 farms with sales of over \$5,000 each. Another 178 farms had sales of \$2,500 to \$4,999; 353 farms had sales of less than \$2,500. The live-stock sector was comprised mainly of cattle and pigs. The total number of cattle was 25,271 while the number of pigs was slightly higher at 28,893. The value of farm capital amounted to \$37.6 million. There were 890 trucks, 1,379 tractors, 522 combines and 390 bailers. The field crops consisted of barley, alfalfa and mixtures containing alfalfa, rapeseed, oats, wheat, mixed grains, flaxseed and rye. The most important crops were barley and alfalfa, accounting for 52.47 percent of the acreage devoted to field crops. Table 1 shows the acreage and the average percent distribution of field crops in the county.

The physical features of the county are known to be

MAP OF ALBERTA SHOWING THE LOCATION OF SMOKY LAKE COUNTY

suitable for alfalfa production. The soil group is generally gleyed dark grey and eluviated black. The dominant texture is loam, well drained and the topography is mainly undulating to gently rolling. The area is slightly stony. Moisture and climate conditions are limiting; for example, winter limits the growth and, therefore, harvesting activities, and as a result the alfalfa processing plant is idle for most of the winter months.

This forage crop is sown and grown by farmers who have contracts with the processing plant. The plant then undertakes to cut, haul, process, store and sell the product. The field operations involve the cutting of alfalfa at a specific stage of growth, deleafing and hauling it to the plant. The raw materials are analysed for protein, fibre and vitamin 'A' content, as required by the sales specifications.

The plant is centrally located within the alfalfa growing area. A choice of central location is dictated by the bulky and heavy nature of green alfalfa and the need to minimize the time lapse between cutting and processing. Distance of haul to the plant and management of the harvesting operations have serious cost and product quality implications. In general, plants try to acquire their alfalfa from within a five mile radius and tend to shy away from distances of ten miles or greater.

Alberta Perspective

Accurate statistics on the average and yields of alfalfa in this province are difficult to obtain. The bulk of the species is not grown in pure stands and is used for many purposes. However, according to the 1971 Census, there were 3.2 million acres devoted to perennial hay production in Alberta. Alfalfa or mixtures containing alfalfa accounted for 50 percent of the total hay production. The recent estimate is approximately 2 million acres of seeded alfalfa in Alberta. The Alberta Department of Agriculture has stated that:

From a soil point of view, 80 percent of the cultivated land in the province can produce satisfactory stands of alfalfa without the addition of lime. Assuming that moisture and climate factors would limit profitable production on 30 percent of the agricultural regions, there would be left in the province roughly 50 percent of the cropland or 15 million acres well suited to grow alfalfa at least in rotation with other crops. Even a rotation requiring a very conservative 20 percent of the land in alfalfa, it is realistic to have a minimum 3¹ million acres readily available for alfalfa.

Alberta's alfalfa production potential is good. According to published statistics on acreage devoted to alfalfa and alfalfa mixtures, Alberta has the highest acreage in Canada. Table 2 shows the acreage of alfalfa and mixtures containing alfalfa by province in descending order of importance.

Markets for Alfalfa Products

Several studies¹ have extensively covered the analysis of market outlets available for alfalfa products in this province. These previous studies analysed both the domestic and international markets. The domestic market was divided into two major outlets:

(1) purchases by commercial feed mills, and

¹ Quintex Engineering Ltd., Boyle Forage Processors Ltd. Feasibility Study for a Forage Processing Enterprise, (Edmonton: Quintex Engineering Ltd., 1972); Department of Agriculture, op. cit.

- (2) individual use for farm and feedlot.

The international market analysis was confined to examining the three main areas which at present appear to be significant in alfalfa trade:

- (1) The West European trade,
- (2) The U.S. market as a main supplier, and
- (3) The Japanese market, which is the largest of all.

A consideration regarding both the domestic and international markets is that processed feeds are in direct competition with home grown feeds such as hay, alfalfa and grain. Unless the product has some specific attraction, the price of alfalfa products will be governed by the equivalent price of other commodities. Another consideration is that new products, as in the case of the alfalfa processing industry in Alberta, must break into the already established market. As such, sales strategy must be developed with strong emphasis on quality as the basis for competition.

The alfalfa nutrient analysis and the comparisons of alfalfa prices and the prices of other ingredients have been intended to convince prospective foreign buyers and the individual farmer of the advantages resulting from the use of alfalfa supplements compared with other feeds. Direct contact has been made usually with individual farmers and big domestic buyers such as feedlots and with foreign buyers. Table 3 shows purchases of legume and grass meal by flour and feed manufacturers in Alberta. Tables 4 and 5 give sales for domestic non-

resale use and direct sales to consuming units for a number of alfalfa processing plants.

The Western European Trade

The European Economic Community is another potential market for alfalfa products. This market is as yet insignificant but the trends show that consumption of alfalfa products may be expected to rise. Available statistics indicate that of the total consumption of 1.2 million tons of dried grass meal in 1971/72, less than 75,000 tons originated from outside the Common Market. However, the European countries have only recently entered into the processing era and it will take time before they achieve self-sufficiency in meeting their requirements of protein concentrates. As such, the EEC is not looked at as a potential supplier but a potential buyer. As the industry and the livestock sector get accustomed to the use of the product either as an input into prepared feeds or for direct feeding, the potential for export of Canadian alfalfa products to these countries becomes real. However, at this time the agricultural industry in the EEC is protected by tariffs against imports of non-member countries.

The Japanese Market

The largest market for alfalfa products from Alberta is Japan. Contacts to explore the Japanese market are made through Japanese representatives in Canada, feed brokers, and the Provincial and Federal Government agencies which organize missions to foreign countries. Tables 6 and 7 show the total imports of alfalfa meal and pellets to Japan and the countries

of origin. U.S. leads all the countries in exporting alfalfa meal and pellets to Japan while Canada is the second largest exporter.

The U.S. Market

The U.S. Market is looked at as a supplier only. The U.S. is by far the largest producer and consumer of dehydrated alfalfa. The American alfalfa industry has developed over a long period of time, but a steady decline in production appears to have set in and, as such, U.S. will not meet the needs of the world market for alfalfa products. It is therefore hoped that Canada will obtain a bigger share of the market.

CHAPTER III

CASH FLOW ANALYSIS

Concept of Cash Flow

One of the objectives of this thesis is to determine the financial viability of the Smoky Lake Alfalfa Processing Plant. Cash flow analysis provides a framework within which viability can be measured and judged. The use of a measure of cash flow emerges under at least seven different circumstances.¹

1. In the literature of investments and security analysis.
2. In the statistics presented in the financial reviews and other similar sections of the annual reports of corporations.
3. As part of a title of a cash flow statement.
4. As the designation of the funds provided from operations in a funds statement.
5. In discussions of rate of return analysis, payback analysis in capital budgeting, and other similar managerial techniques where it is part of such expressions as "discounted cash flow."
6. With reference to cash projections of cash budgeting.
7. In the expression "Cash Flow" system, which refers to the control of cash in and out of a business in the pro-

¹ Perry Mason, Cash Flow Analysis and the Funds Statement. Accounting Research Study No. 2 (New York: American Institute of CPA's, 1961), p.3.

motion of efficient creation and use of cash balances.

The concept of cash flow as the definition of the best measure of viability in project analysis is used by Little and Mirrlees.¹ For every year all expected expenditures on goods and services for the project and all expected receipts from the project are recorded. For each year, the subtraction of the former from the latter shows how much cash the firm gains or loses as a result of the project. Table 7 contains a detailed derivation of cash flow accounting.

The accounting technique contained in row 11 of Table 7 is only applicable to a new investment. "Borrowing and lending, and interest or dividend payments," according to Little and Mirrlees, "are normally excluded from the concept of cash flow when this is used for the purpose of assessing the profitability of a new investment."² Row 12 is the accounting technique relevant for assessing a project from the point of view of society. Alternatively, this technique is employed in economic analysis of investment projects for public benefits.

In economic analysis of investment projects for public benefits, income taxes, sales taxes and custom duties are transfer payments within the society, not payments for resources used in production. They are not deducted from the stream of benefits when deriving the cash flow, which is the basis

¹ Ian M.D. Little and James A. Mirrlees, *Manual of Industrial Project Analysis in Developing Countries: Vol. II*. Paris: Development Centre of the Organization for Economic Cooperation and Development, 1968.

² Ibid., p. 18.

on which the productivity of capital will be computed. For the purpose of this study, the accounting technique contained in row 9 is applied to assessing the financial viability of Smoky Lake plant. The plant is privately owned and therefore taxes are a cost which the individual entity must pay before arriving at the amount available for recovering its capital and compensating it for the use of its capital.

There is another difference between assessing profitability of public investment as opposed to the private. The analysis for private investment treats borrowed capital as it is received into the receipt streams as a kind of benefit received. When payments of interest or repayment of principle is made to the outside supplier of capital, it is deducted from the gross return as a cost in deriving the cash flow. The same treatment of borrowing can only be applied to the economic analysis of the public investment when foreign capital is involved because of the assumption that all resources employed in the project belong to someone within the society. Therefore, borrowing does not enter into economic analysis of public projects when there is no foreign capital involved.

The assessment of a project from the point of view of society is recognised by Gittinger in his definition of cash flow. According to Gittinger:¹ "When we look at a project we can see it as earning a stream of gross benefits from which

Add Indirect Taxes on Inputs	T*
12. Social Cash Flow	R-C-K+T*

we must deduct the capital investment and pay the other input costs -- the machinery, fertilizer, pesticides, labour, management-consultants, etc. What is left over is a residual that is available to recover the investment made in the project (the return of capital), and compensate for the purpose of the money involved in the project (the return to capital or on capital)." This residual is termed cash flow.

The major common characteristic of all cash flow concepts is that they include undifferentiated return of capital and return to capital. Therefore, to compute the cash flow, no allowance for depreciation is deducted from the gross returns.

Depreciation

In accounting, depreciation is defined as the allocation of the cost (purchase price minus salvage) of an asset which will be used up over a long period of time by charging a portion of the cost to each period of expected life. But to compute the cash flow, deduction from the gross return of any allowance for depreciation, that is, return of capital, is not done because the analytical technique will take care of the return of capital in determining the value of the project. In the same way, when determining the gross cost stream for calculating discounted measures of the project value, depreciation is not included as a cost (that is, return to capital) in spite of the fact that internal rate of return is a measure of the capacity (return to capital), while net present value determines if the project can earn more than some stated amount of

return to capital. However, the return to capital is realised (depreciation is covered and fully accounted for) when the project earns an internal rate of return of zero or greater, when the net present value at zero discount rate is zero or greater, or when the benefit cost ratio is one at a zero or greater rate of interest.

Discounted Cash Flow

Cash flow projections applied to investment viability issues such as the Smoky Lake alfalfa plant are generally discounted. Discounting is common practice because a dollar in hand today is believed to be more valuable than a dollar to be received in the future. Therefore, future cash flows cannot be aggregated with equal weights. For the purpose of aggregation, a rate of discount must be selected. This is a rate of return which, given the financial conditions for obtaining cash and the investment opportunities likely to be open to the firm in future years, is considered necessary to earn on the new investment.

The process of discounting is compound interest worked backwards. Expenditures and receipts which occur at different times are all revalued to make them comparable to present expenditures and receipts. They can be added up to give a single figure, the "present value". It comes to the same thing to subtract expenditures from receipts to give a cash flow for each year and then discount the cash flows back to the

present. In general, the formula applied to discount the future cash flows back to the present is given by:

$$PV = \frac{FV}{(1+i)^n}$$

where: PV = present value,

FV = future value,

i = interest rate,

n = number of years.

Choosing the Discount Rate

According to Gittinger, for the purpose of analysing public projects:

The most appropriate rate is the opportunity cost of capital-- that rate which will just result in all the capital in the economy being invested if all possible projects were undertaken which yielded that much or more return. If set perfectly, the rate would just reflect the choice made by society as a whole between present and future returns, and hence, the amount of total income the society is willing to save.¹

In the case of private investment, the most appropriate rate is that rate which is more or less close to the rate at which the firm can borrow, usually, the market rate of interest. In common practice, for both public and private projects, there are problems associated with establishing this rate.

It is suggested that the discount attached to future returns by the society as a whole is different from that which individuals use. It is felt that society has a longer time

¹ Ibid., p. 90.

horizon so its discount rate is lower. This implies differing rates of interest for public and for private projects. But, according to Nichols, "there is little agreement among economists on how that rate should be chosen."¹ In practice, the rate chosen is simply a rule of thumb although most countries believe it is between 8 and 15 percent.

Alternative Measures of Viability

The use of a measure of cash flow emerges under various methods. The most commonly used are the benefit/cost ratio and the internal rate of return.

Benefit/cost ratio is a ratio of benefit to cost in which estimates of benefits and costs of a project accruing at various times are made comparable through adjustment to a uniform basis using a discount or interest rate. The estimation of costs and benefits involves the listing and consideration of as many effects as can be identified and all persons and groups likely to be affected, however remotely, by a project. For the purpose of determining the financial viability of the Smoky Lake alfalfa plant, the benefit/cost ratio technique is not applied because, according to Gittinger: "The benefit/cost ratio is used almost exclusively as a measure of social benefit, and most commonly for water resource projects. It is almost never used for private investment."² However, when the benefit/

¹ D.A. Nichols, "The Public Discount Rate". Madison: University of Wisconsin, June 1974, p. 1 (Mimeograph).

² J. Price Gittinger, op. cit., p. 60.

cost ratio is used, the project should have a ratio of one or greater to be justified.

The internal rate of return is defined as the rate of discount which makes the present value of the project zero. The value represents the average earning power of the money used in the project over the project life. The earning power is important because entrepreneurs and other investors are more used to judging investments by their yield rather than by either of the other measures. Because of the general acceptance of the internal rate of return, this measure has been applied to the Smoky Lake alfalfa plant.

The formal selection criterion for the internal rate of return measure of a project value is to accept all projects having an internal rate of return above the opportunity cost of capital. One cannot randomly select that discount rate which will make the cash flow equal to zero. There is no formula for finding the rate of return, therefore one must resort to trial and error.

The trial and error method begins with a discount rate which a quick guess indicates might be in the right neighborhood. Then, by interpolation one can estimate the true value. Interpolation is finding the intermediate value between the two discount rates (lower discount rate and higher discount rate). The rule for interpolating the value of the internal rate of return which lies between discount rates too high on

one side and too low on the other is given below:

Internal Rate Lower Difference
of Return = Discount + Between
 Rate the Discount

Present Value of Cash Flow at the Lower Discount Rate.
Absolute Difference Between the Present Value of the Cash Flow at the Two Discount Rates.

Limitations of Cash Flow Concepts

The cash flow accounting concept differs from normal accounting terminology because cash flow accounting excludes depreciation. As such, the use of cash flow accounting is controversial and has not been completely accepted by accountants. For example, Perry Mason, writing a critique of cash flow analysis, states that:

The concept of cash flow as the amount of funds derived from operations (net income plus depreciation, etc.) can serve as an effective analytical tool. The discussion, presentation and interpretation of cash flow data is, however, often inadequate and sometimes inaccurate and misleading.¹

In accounting terminology, depreciation is a cost because a depreciable asset uses funds in the period in which the acquisition takes place. This cost must be covered during

¹ Perry Mason, Op. cit., p. 30.

the scope of the depreciable asset's life by the excess of revenue over operating costs other than depreciation on that asset if a loss from operations is to be avoided. In other words, depreciation is an operating cost or expense and the purpose of depreciation accounting is to distribute the cost systematically over the operating periods included in the useful life of the real assets. On the other hand, it is argued that the annual charges for depreciation and amortization are merely bookkeeping entries and do not represent corresponding outlays of cash. As such, management has considerable discretion in setting aside actual annual amounts of money in the name of depreciation.

Cash Flow Projections

In evaluating a potential investment, one is basically concerned with quantifying the stream of future benefits and costs accruing over a finite planning period. Because future benefits and costs are liable to change over time for exogenous reasons, the eventual outcome may be quite different from the outcome originally anticipated. Some of these exogenous reasons include risk and uncertainty, and in most cases, inflation. It is suggested that the only realistic assessment of the future is that inflation will continue. The problem therefore becomes one of how to cope with inflation in making realistic projections such as those required for the Smoky Lake alfalfa plant.

There are several approaches to projections that can

be utilized to cope with inflation. Although none of them serve as a panacea, it is the function of a science to make predictions and any procedure that can help in making a better guess concerning the future is of practical importance. Below are some of the approaches that can be applied to determine future prices and costs:

- (1) Inflate all costs annually by what you think will be an average rate of inflation.
- (2) Assume that all prices on both the outflow side and the inflow side will rise uniformly by the same proportion and that they will therefore not change their relative values.
- (3) Assume constant prices for all items except the ones you think will be affected disproportionately by inflation. Prices for the latter group of items are increased or decreased to reflect relative changes in prices arising from the differing impact of inflation.

For the purpose of cash flows projection of the Smoky Lake alfalfa plant, the latter method was adapted. It is believed that the impact of inflation on items such as labour costs and fuel is significantly more noticeable than that on items such as licence and property tax.

Data

The data used for the projections were obtained from Smoky Lake Alfalfa Processors Ltd. Financial Statements¹ for

¹ Clarkson, Gordon and Co., Chartered Accountants, "Smoky Lake Processors Ltd. Financial Statements, March 31, 1972, 1973, 1974 and 1975." (Mimeographed.)

the years of 1972, 1973, 1974 and 1975. The main parts of these financial statements were:

- (i) the statement of income,
- (ii) the statements of deficit; and
- (iii) changes in financial position for the year then ending.

For the purpose of cash flow projections, the above statements were not suitable. They were rearranged to achieve consistency. Fixed costs were separated from variable costs. In economics, usually a distinction is made between fixed and variable costs. Fixed costs are those costs of a business which go on regardless of the amount of production while variable costs are those expenses of a business or industry that vary with the amount of business done or the volume of goods processed. The equivalent of fixed costs, as presented in the financial statements, were the administrative costs. The cost of goods processed corresponded to the variable costs. However, the cost of goods processed contained several items such as licences, utilities and spur-line rental which did not vary with the volume of goods processed. These more or less fixed costs were therefore classified with the administrative costs for purposes of the cash flow analysis. All these fixed costs, with the exception of the management salaries, were assumed constant while the variable costs were increased to reflect changes in prices.

Fixed Costs Projections

A list of items for which future prices have been assumed constant is contained in Table 8.¹ The cost of each item is given for the four years 1972-1975. For the purpose of cash flow projections, those costs which occurred in 1975 provided the projection base; 1975 was chosen because the plant has only recently been established. This projection base also applied to variable costs projections. The range in these fixed costs is such that an average of four years is evidently distorted. After a period of four years of plant operation, it is believed that almost true cost values have been established.

In order that the assumption of constant prices be strengthened, each item has been documented. The following is how each item has been handled.

1. Licence fees: This item is a fixed cost to the plant, payable once a year. The cost of licencing plant operations has remained almost unchanged since the beginning of operations four years ago. This trend is assumed to hold so that no significant change can affect the cash flow.

2. Telephone charges: An increase in telephone rates was announced recently by the Public Utilities Board. However, the Board asserts that this increase cannot be relied upon as a 'forecast indicator' because the past rates have not been

¹ The only exception is management salaries.

TABLE 8

THE FIXED COSTS: SMOKY LAKE
ALFALFA PROCESSORS LTD., 1972-1975

Item	1972 \$	1973 \$	1974 \$	1975 \$

"Smoky Lake Processors Ltd. Financial Statements,
March 31, 1972, 1973, 1974 and 1975." (Mimeographed).

characterised by any significant changes.¹ Therefore, in this analysis, the cost of telephone is held constant partly because of this historical trend and partly because any possible increases, given the small size of the plant, would have no significant effect on cash flow.

3. Advertising costs: Advertising, as practised by the management body of any alfalfa enterprise in this province, is aimed at providing information, especially to cattle feeders. The Management Body of Smoky Lake Alfalfa Processing Plant are not thinking about any drastic changes that might alter this policy. Because of this intent, there are no added advertising costs expected. Therefore, the current cost is assumed constant in this analysis.

4. Travel costs: These costs may not be avoided at certain times. The manager is expected to attend meetings, conferences or seminars which concern the alfalfa enterprise. Such travels, however, are mainly within the Province of Alberta and are therefore not costly. The cost of travel up to the present has ranked as one of the smallest expenditures since the plant went into operation. It would therefore seem safe to assume a constant cost in the analysis.

5. Office expenses: These include the purchase of office equipment, stationary and general office supplies. Most of the equipment was bought at the beginning of operation. The nature of the business is such that it does not require

¹ Interview with R. Atkinson, Economist, Public Utilities Board, Edmonton, Jan. 15, 1976.

expensive office equipment. The expected future costs will arise out of the need to replace equipment that is broken or lost. As such, the expenditure on this equipment is not expected to constitute any sizeable amount that might erode the financial standing of the enterprise.

6. Utilities: Utilities consist of water supply and electricity. The Public Utilities Board asserts that the historical trend has not shown increases beyond the average rate of inflation. This trend is assumed to hold, so that the cost of utilities is projected without disproportionate changes in cost.

7. Spur-line rental: The cost of renting the spur-line has remained fixed since the plant started operating. The present facilities provided by the spur-line are capable of handling full capacity production of the plant. As such, there is no need to rent a second spur-line and, therefore, no additional costs are incorporated in the projection.

8. Management salaries: Management salaries do not depend on the volume of output. Nevertheless, management salaries are expected to increase at a rate beyond the rate of inflation. A percentage increase of 5.4 percent¹ has been assumed in determining the annual increase expected by the management body.

¹ According to Statistics Canada, the price index for wages was 105.4 percent in March 1975 over that of March 1974, taking the latter period as the base at 100 percent. Statistics, Canada, Prices and Price Indexes, Cat. No. 62-002. (Ottawa: SC, 1975). The 5.4% is not related to productivity (Productivity is assumed constant). Management is expected to maintain its labour force more or less at the same level.

9. Insurance: Insurance costs have increased about 40 percent since the Smoky Lake plant went into operation (1972). This increase, according to the Treasurer of the enterprise, is attributed to the increase in field equipment (harvesters, trucks, etc.) acquired over the period. The required number for full capacity production has been obtained. Future additions to equipment are expected to be limited to replacements, and so insurance coverage should remain constant.

Insurance premiums, while vulnerable to radical change as evidenced by recent hikes, are expected on average to remain within average inflation levels. According to Mr. Cooper¹ of the Insurance Bureau of Canada, the recent premium increases are not a good forecast indicator. The past ten years have been characterised by negligible changes in rates.

10. Property tax: The bases on which taxes are levied are:

- (a) a percentage of the assessed value of real property,
- (b) the assessed annual rental of immovables and the area of premises occupied for business purposes, and
- (c) the value of stock-in-trade.

On these bases, property tax levied on the Smoky Lake Alfalfa Processing Plant is expected to remain stable. The nature of the business is not going to be changed and mill rates are constrained by voter acceptance. The property tax paid in 1975

¹ Personal Interview with R.A.S. Cooper, Alberta Manager, Insurance Bureau of Canada, Edmonton, Jan. 15, 1976.

was actually less than that of 1974.

Variable Costs Projections

An explanation as to how the projection base was arrived at has already been given.¹ As already stated, it is assumed that variable costs will be affected disproportionately by inflation and will vary with the volume of goods processed. These two considerations provided the basis on which to calculate the future variable costs. A list of variable costs since 1972 for the Smoky Lake plant is given in Table 9 and Table 10 shows throughput coefficients applied to those variable items in terms of cost per ton processed. These coefficients are averages of the past four years. Each variable cost has been documented and treated separately.

1. Cost of raw material: The cost of raw material will increase as the plant approaches full capacity, and will level off thereafter. Raw materials are based on a technical transformation rate of three tons of fresh cut forage to one ton of pellets. A ton of wet forage is valued at \$25.² A 75 percent full capacity output of 12,000 tons of alfalfa pellets requires 36,000 tons of raw alfalfa at a cost of \$900,000.

2. Wages and benefits: The wages and benefits will increase with output and will be affected disproportionately

¹ Refer to section on fixed costs projections.

² The price paid for wet alfalfa fluctuates year by year depending on the availability. But for the last three years (1973-1975) the price has not exceeded \$22 per ton. The assumed price of \$25 per ton is expected to accommodate future increases in price.

Bad Debt Expenses	0.13

Source: Computed from Clarkson, Gordon and Co., the Smoky Lake Alfalfa Processors' Financial Statements for the year ending 1972, 1973, 1974 and 1975.

by inflation. Both considerations are incorporated in the cash flow projections. The percentage increase of 5.4 percent per year is used to inflate the technical labour value input/output coefficient of \$10.40 per ton of pellets. The projected labour costs will be subject to the allowance for disproportionate wage inflation and assumptions about the level of production.

3. Freight charges: The cost of freight and handling is a function of the level of processing. When the projected capacity is achieved, the cost of freight and handling is not expected to change significantly. Therefore, the throughput coefficient in terms of cost per ton processed, that is, \$4.16, is applied in the analysis.

4. Natural gas: The cost of natural gas is expected to increase with output as well as because of market price changes. The throughput average cost coefficient per ton for 1972-1975 was \$2.36. When the projected capacity is reached, the only factor taken into account will be that for disproportionate natural gas price inflation.

5. Cost of rapeseed oil: The amount of rapeseed oil required will depend on the level of processing, but the cost of rapeseed is not expected to increase at a rate beyond the rate of inflation. "There is a great likelihood," according to Gittinger, "that the relative price of agricultural products will remain as much as it has been in the past. Only when there is a clear-cut case for changing the relative prices would it

seem justified to abandon the assumption that relative prices of agricultural products will remain the same."¹ Therefore, the projected cost of rapeseed will be subject to the assumption about the level of production and when the plant approaches full capacity, the cost of rapeseed oil will not be significantly affected by the rate of inflation.

6. Cost of equipment repairs: The amount of increase in equipment will depend on the level of business. But since the required number for full capacity production has already been obtained, the cost of equipment would be expected to remain fairly constant. However, repair work involves the use of labour. Because labour costs compose a high proportion of repair costs, the cost of repairs is expected to be affected disproportionately by inflation. The projected repair costs are based on the average throughput coefficient of \$4.61 adjusted by an allowance for disproportionate wage inflation.

7. Cost of field equipment rentals: Field equipment consists of harvesters and trucks. The plant rents field equipment in addition to what it owns. In most cases, an increase in purchases of green alfalfa makes it necessary for Smoky Lake alfalfa processors to rent field equipment to supplement their own. Therefore the cost of field equipment will increase as the plant approaches full capacity, and will level off thereafter. The average throughput cost coefficient was \$1.06 per ton from

¹ J. Price Gittinger, op. cit., p. 35.

1972-1975. The future cost increase of equipment rental is expected to be limited to this coefficient.

8. Bad debt expenses: It seems reasonable to assume that increased output will lead to more financial transactions. Good financial management should keep bad debts to a minimum and records so far show little problem with bad debts. However, bad debts are also due to the number of transactions. Therefore, the cost to the plant of these bad debts is expected to increase with the volume of output; when the projected capacity is achieved, the cost of bad debts is expected to remain constant.

Current Inflows

The current inflows for the Smoky Lake plant are classified under two categories:

- a) the amount of pellets sold; and
- b) the value of inventory.

Table 11 shows the actual current inflows for the period 1972 to 1975 inclusive. The approach taken to project these current inflows is documented below:

1. The amount of pellets sold: The annual throughput of the Smoky Lake Alfalfa Processing Plant has ranged between 3,335 tons and 7,734 tons of pellets since the plant started production in 1972. Most alfalfa plants with the same capacity (16,000 tons) in this province have been able to produce 12,000 tons in their second year of operation. An example is provided

by the Falher Alfalfa Company Ltd., where two shifts per day with a throughput of 80 tons per shift have been achieved by the second year of operation. Given 100 days of operation annually and 160 tons per day, the current annual throughput of the Falher plant amounts to 16,000 tons. It is therefore possible that the same amount could be achieved by Smoky Lake alfalfa processors; however, the first four years of operation cannot make one optimistic about achieving a throughput of 16,000 tons. Therefore, the most likely projection of revenue, given the price, is based on the assumption that only 75 percent of capacity will be utilised.

The price per ton of pellets was \$55 in 1973. In 1974 there was a considerable increase when the price per ton went to \$70. Another increase in price to \$85 was experienced in 1975. The market situation has therefore been favourable; but, it is asserted that there was a shortage of animal protein, especially in 1974. Since, then, the situation is believed to have improved and for the purpose of revenue projection in this study, the most likely price is assumed to be \$70 per ton.

TABLE 11

CURRENT INFLOWS: SMOKY LAKE ALFALFA
PROCESSING PLANT, 1972-1975

Item	1972	1973	1974	1975
Pellets Sold	82,245	290,405	507,668	323,017
Value of Inventory	24,929	63,581	59,862	166,770
TOTAL	107,174	353,986	567,530	166,770

Source: Clarkson, Gordon and Co., Chartered Accountants, "Smoky Lake Processors Ltd. Financial Statements. March 31, 1972, 1973, 1974 and 1975." (Mimeographed.)

2. Value of inventory: The value of inventory is that of unsold output. This output is held in the normal inventory and is ready for sale. It is therefore treated as a current revenue in the year it is produced rather than in the year it is sold. For the purpose of projecting the value of inventory, it is assumed that 1,000 tons, valued at \$70,000 will be maintained.

Capital Outflows

Capital outflows represent the amount spent on capital goods such as buildings and storage. In common practice, capital outflows occur at the beginning of the investment. Table 12 shows that most of these outflows took place in the first year of plant records.

TABLE 12

CAPITAL OUTFLOWS: SMOKY LAKE ALFALFA PROCESSING PLANT, 1972-1975

Item	1972 \$	1973 \$	1974 \$	1 75 \$
Plant and Field Equipment	281,673	6,537	-	110,835
Buildings and Storage	224,995	-	47,086	-
Plant Site	46,871	-	-	-
Development Costs	48,685	1,705	-	-
Power Generators	70,462	-	-	-
TOTAL	672,688	8,242	47,086	110,835

Source: Clarkson and Gordon and Co., "Smoky Lake Alfalfa Processors Financial Records, March 31, 1972, 1973, 1974 and 1975." (Mimeographed.)

In the cash flows projections, outflows were related to capital items that have a short span of life. The expected life of buildings is twenty years while the assumed life of field equipment and power generators is five years and ten years, respectively. Therefore, in projecting capital outflow, some amount of money has been phased at intervals of five years for field equipment and ten years for power generators. This treatment is not extended for buildings with a life span of twenty years since the planning period covers fifteen years.

Capital Inflows

Capital financing was obtained through borrowing and from share equity capital. Borrowing consisted of one long term loan of \$400,000 and an incentive loan of \$135,000. The company is not expected to pay either interest or repayment on principle for the incentive loan.

The long term loan from Alberta Opportunity Company was approved in 1972, but since construction and equipment were made in 1971, the company was authorized to borrow short term monies from commercial banks. These loans were paid off when the long term loan arrangements were completed in 1972. As such, the cash flow analysis includes only the amount of the long term loan. But, the bank charges on the interim borrowings are included since they were real cash outflows.

Since the long term loan for the plant was approved, the processors have continued to borrow short term monies, It

1986	33,007	4,375	41,136	-	45,511
1987	-	1,093	33,007	-	34,100

has been considered realistic that this trend could continue. However, for the purpose of this study the trend is assumed to end in 1981 and the phasing of interest on short term loans covers the period from 1972-1981.

On the long term loan, a rate of interest of 8 percent plus repayment of principle are paid annually. The arrangement made with the Alberta Opportunity Company is that the loan must be fully paid for by 1987. The phasing of interest and repayment of principal is extended to that year. The projected loan repayment schedule is contained in Table 13.

Sensitivity Analysis

One of the real advantages of careful economic analysis for either public investment or private investment, is a test of what may happen to earning capacity if something goes wrong. For the purpose of this analysis several assumptions with respect to varying both capacity and price were applied to gain an insight into what would happen if the pellet price was lower or higher than the \$70 projected. In the same way, the actual throughput percentage of capacity could be less or more than the 75 percent projected. The following assumptions were applied to determine the sensitivity of the plant's financial viability to different circumstances.

1. The price per ton of pellets was set at \$50 and was then applied to throughput of 40 percent, 60 percent, 75 percent and 95 percent capacities.

2. The price of \$70 per ton of pellets used to derive the most likely current cash inflows at 75 percent of capacity in the cash flows projections was applied to throughput of 40 percent, 60 percent and 95 percent capacities.

3. The price per ton of pellets sold was increased to \$100. This price was then applied to the throughput percentages already cited.

A shortcut procedure for the necessary computations was followed. The 75 percent throughput capacity used for the most likely cash flows projections provided a base to compute changes in variable costs according to the capacity levels of 40 percent, 60 percent and 95 percent. The fixed charges were not altered.

Results of Cash Flow Projections

The results for the most likely cash flows projections for Smoky Lake plant are contained in Table 14. The annual totals are summarized in Table 15. Over the projected period, total inflows are more than total outflows by \$2,448,031. The discounted cash flows for each year are contained in Table 16. The discounting rates vary from 5 percent to 16 percent.

A positive net present value holds at the discounting rate of 5 percent and at the subsequent rates of interest up to 15 percent. At a discount rate of 16 percent, the net present value is negative (-\$33,166), but at a rate of 15 percent, the net present value is greater than zero at \$6,431. Table 17

TABLE 17

THE EFFECT OF THE CHANGING RATE OF INTEREST
ON THE NET PRESENT VALUE: SMOKY LAKE PROJECTED
CASH FLOWS

Cash Flow Discounted by	Net Present Value
(%)	(\$)
5	793,028
6	662,202
8	452,954
10	287,119
12	155,400
14	51,581
15	6,431
16	-33,166

shows the effect of the rate of interest on the net present value. If the rate of interest was 16 percent, it would pay to invest in the alternative project because a negative net present value would mean a loss to the investor.

The internal rate of return was defined as the rate of discount which makes the present value zero. On this basis, the rates of 15 percent and 16 percent were interpolated to obtain the true rate of return. The formula for interpolation is reproduced for convenience as follows:

Internal	Lower	Difference
Rate of	= Discount	+ Between
Return	Rate	the Discount

Present Value of Cash Flow at the Lower Discount Rate
Absolute Difference Between Values of Cash Flow at the Two Discount Rates

$$\begin{aligned}
 R &= 15 + 1 \left(\frac{6431}{39597} \right) \\
 &= 15 + 1 (0.2) \\
 &= 15 + 0.2 \\
 &= 15.2 \%
 \end{aligned}$$

Thus, the internal rate of return is 15.2 percent for the Smoky Lake Processing Plant, with a throughput of 75.0 percent capacity and a selling price of \$70 per ton of pellets. The plant is capable of earning back all the capital and operating costs expended upon it as long as the opportunity cost of capital is less than 15.2 percent.

Results of Sensitivity Analysis

The results of the sensitivity analysis are based on the three assumptions already stated. Using varying prices and capacities, the results of undiscounted cash flows are contained in Tables 18, 19 and 20.

According to Table 19, the output necessary for the plant to cover all costs at the price of \$70 per ton of pellets lies somewhere between throughputs of 40 and 60 percent of capacities. But if the price per ton of pellets was \$100, according to Table 20, the plant would realize a positive cash flow at a 40 percent level of throughput capacity. The specific values will appear later in graphic presentation.

Following the sensitivity analysis, the earning power of Smoky Lake plant is shown in Table 21. At the most likely price of \$70 per ton of pellets, the earning power of the plant could increase to 22 percent if the throughput were raised to 95 percent of full capacity, or 15,200 tons per year. Alternatively, the yield would be negative if the throughput was 40 percent of capacity. At the price of \$50 per ton of pellets, the financial rate of return is negative at all levels of throughput. On the other hand, at the price of \$100 per ton of pellets, the financial rate of return for the plant is very attractive, even at the throughput of 40 percent capacity.

The results for both the most likely projections and the sensitivity analysis are presented below in graphical form.

TABLE 21

THE FINANCIAL RATE OF RETURN DUE TO
 VARYING PRICE AND THROUGHPUT:
 SMOKY LAKE ALFALFA PROCESSING PLANT,
 1972-1990

Price per Ton		Financial Rate of Return			
(\$)	Throughput at 40% Capacity	Throughput at 60% Capacity	Throughput at 75% Capacity	Throughput at 90% Capacity	
50	0	0	0	0	
70	0	10	15	22	
100	19	28	33	38	

Figure 4 indicates the relationship between the set pellet price of \$50 per ton and the varying throughput percent of capacity. The total cost curve lies above the total revenue curve and the fixed costs are not covered unless throughput exceeds 18 percent of capacity. When the pellet price is set at \$70 (Figure 5), the total cost curve lies above the total revenue curve only at a throughput of equal or less than 46 percent of capacity; beyond that level of throughput, the total revenue curve lies above the total cost curve. Therefore, given the pellet price of \$70 per ton, total costs will be covered only if throughput percent of capacity exceeds 46 percent. On the other hand, according to Figure 6, if the price was raised to \$100, a throughput capacity of 26 percent would ensure that the plant does not lose or gain any monies.

A historical throughput and throughput percent of capacity has been included for the purpose of comparison. Table 22 gives the actual throughput and throughput percent of capacity for Smoky Lake Alfalfa Processing Plant based on a throughput of 16,000 tons per year. Table 22 also shows the actual throughput percent of capacity based on the assumption of 12,000 tons per year. According to the most likely assumption on throughput of 12,000 tons per year and a pellet price of \$70 per ton, the actual average percent of capacity is 50.74 percent which is just above the 46 percent of capacity required for total revenue to equal total costs.

CHAPTER IV

A MODEL FOR REGIONAL ECONOMIC IMPACT ANALYSIS

Linear Programming Models

Examination of the competitive impact of alfalfa production on other farm enterprises in Smoky Lake County and the regional impact of the Smoky Lake Alfalfa Plant are objectives of this study. A linear programming model for Northern Alberta agriculture¹ is employed for the purpose of examining this economic impact.

Linear programming is a computational technique used to determine in numerical terms optimum allocations of resources required to reach a stated objective. In other words, linear programming provides a method for allocating the best plan for achieving the stated objectives in a situation in which resources are limited. In general, therefore, a problem of linear programming is that of finding non-negative values of a number of variables for which a certain linear function of those variables assumes the greatest (or the least) possible value while subject to certain linear inequalities.

The first explicit use of linear programming techniques occurred in connection with the planning activities of the United States Air Force during the period immediately following

¹ L.P. Apedaile, "A Model of Agricultural Technology for Policy Analysis in Northern Alberta. Interim Report, March, 1975." (A report written for Alberta Agriculture Research Trust Grant 55-28025).

World War II.¹ It was, Dantzig who formulated the general linear programming problem and developed the simplex method of solution. As often happens, however, the development of novel tools of analysis suggested applications in fields that were quite different from those to which the tools were initially intended to apply. Since that time the subject has received widespread application in both industry and government.

Linear programming has been used as a research tool by agricultural economists to:

1. Specify the optimum organization of resources and enterprise on farms.
2. Suggest desirable farm adjustments.
3. Specify profit maximizing mixes of commodities produced by marketing firms.
4. Specify cost minimizing methods of processing products such as fertilizer or mixed feeds.
5. Specify spatial equilibrium patterns in the flow of agricultural products to indicate optimum interregional patterns of resource use and product specialization in agriculture and to solve related types of problems.²

Assumptions

Several assumptions are used in linear programming.

Heady and Candler warn, however, that "if these assumptions do

¹ Full details are given in G.B. Dantzig, "Maximization of a Linear Function of Variables to Linear Inequalities." Activity Analysis of Production and Allocation, edited by T.C. Koopmans, (New York: McGraw-Hill Book Company, Inc., 1951), pp. 339-347.

² Earl O. Heady and Wilfred Candler. Linear Programming Methods (Ames: Iowa State University Press, 1960) p. 7.

not apply to the problem under consideration, linear programming may not provide a sufficiently precise solution."¹ Their assumptions are stated below:

1. Additivity and Linearity: The activities must be additive in the sense that when two or more are used, their product must be the sum of their individual products. An equivalent statement is that the total amount of resources used by several enterprises must be equal to the sum of the resources used by each individual enterprise. Thus, no interaction is possible in the amount of resources required per unit of output regardless of whether activities are produced alone or in various proportions. Similarly, increasing returns to scale for single processes are not allowed, since equal additional inputs do not add equal amounts to output.

2. Divisibility: It is assumed that factors can be used and commodities can be produced in quantities which are fractional units. That is, resources and products are considered to be continuous-- to be infinitely divisible. Linear programming will therefore specify a program of activities which uses .7 of the land or .994 of the labour supplies available. They go on to say that this assumption is not a serious limitation since a program ordinarily can be rounded to include activities produced to the nearest whole unit without causing serious decision-making errors.

¹ Ibid., pp. 17-18.

3. Finiteness: It is assumed that there is a limit to the number of alternative activities and to the resource restrictions which need be considered. This is a practical assumption. If the farmer, businessman, or planner had a unlimited number of alternatives, he would never have them programmed because he could never finish the computational task of determining the most profitable programme.

4. Single-Value Expectations: In general, the linear programming methods used widely to date employ the standard linear programming assumption that resource supplies, input-output coefficients, and prices are known with certainty. This assumption is unrealistic for certain farming situations. However, this 'self-secure' assumption is used in conventional research techniques such as budgeting. In this regard, linear programming provides solutions which are as realistic as those from other methods which employ the same assumptions.¹

Problem Formulation

Linear programming problems are generally expressed as follows:

$$\text{Maximize (minimize) } Z = C_1X_1 + C_2X_2 + \dots + C_nX_n$$

Subject to:

$$A_{11}X_1 + A_{12}X_2 + \dots + A_{1n}X_n \quad (=) \quad b_1$$

$$A_{21}X_1 + A_{22}X_2 + \dots + A_{2n}X_n \quad (=) \quad b_2$$

$$A_{m1}X_1 + A_{m2}X_2 + \dots + A_{mn}X_n \quad (=) \quad b_m$$

$$X_i \geq 0 \quad \text{for all } i.$$

$$b_i \geq 0$$

¹ Ibid.

The simplex method is one of the techniques which may be used to find the maximum (minimum) of the objective function subject to the constraints given.

Objective Function

All linear programming problems are concerned with either minimizing or maximizing something. It is not necessary to classify linear programming problems into two types, according to whether the objective function is to be minimized or maximized. This is because every time a quantity is maximized, some other quantity, for example its negative, is minimized. As such, there is no conceptual difference between the two operations.

Given several methods or processes-- different enterprises and different techniques of producing the enterprises-- by which the objective can be attained, we choose from among them the methods or processes which are most efficient in converting resources into the objective.

A linear programming problem also does not exist unless some resources (land, labour or capital) are restricted or limited. For most planning or choice problems there are restrictions which set limits on the kinds of plans that can be considered. Although the fixed resources represent the main type of restrictions, they may also be other restrictions such as institutions.

Solving Linear Programming Problems

There is no known direct method for solving linear programming problems. In view of this fact, solving linear programming problems involves iterative solutions, i.e., solutions are carried out in a number of steps or iterations, each of which brings the problem closer to solution.

Dantzig's simplex method is one of a number of methods of solution in use. Others include the complete description method of Motzkin, Raiffa, Thompson and Thrall and solution by elimination. For unsophisticated problems, graphic methods of solution may suffice. Solution by elimination is not practically useful because it depends on knowing in advance the restraints that will be binding. On the other hand, graphic solution is only practical when there are only two restraints. When the number of unknowns exceeds three, a geometric solution is impossible.

The simplex method makes use of slack or disposal variables which permit us to replace the inequalities by equalities. For example,

$$a_{i1} + x_1 + \dots + a_{in}x_n \leq C_i$$

Suppose this inequality is replaced by the equation:

$$a_{i1} + x_1 + \dots + a_{in}x_n + x_{n+i} = C_i$$

where:

$x_{n+i} \geq 0$ and conversely, the new variable x_{n+i} is known as a slack variable because it merely accounts for the excess

of the right hand side over the left hand side.

Computational Procedures

The starting point in linear programming is to obtain the basic data and define the problem to be solved (such as maximum output or selecting a combination of enterprises which will maximize profits). In any case, the program selected must be feasible. A feasible program is one which does not have total resource requirements exceeding total resource supplies.

Given the resource supplies and the input-output coefficients, a system of relationships can be established which defines the production possibilities and states the profit function equation.

For example, suppose the problem to be solved is:

$$\text{Maximize } A = 30X_1 + 10X_2 + 40X_3$$

Subject to:

$$4X_1 + 2X_2 + X_3 \leq 100$$

$$X_1 + X_2 + X_3 \leq 120$$

$$10X_1 + 5X_2 - 4X_3 \leq 88$$

and that:

$$X_1; X_2 \text{ and } X_3 \geq 0.$$

In order to apply the simplex method, the inequalities are first converted to equalities. This is done by adding the non-negative slack variable (disposal activity) so that the left-hand side of the equation is equal to the right-hand side of the equation.

For example:

$$4X_1 + 2X_2 + X_3 + X_4 + 0X_5 + 0X_6 = 100$$

$$X_1 + X_2 + 3X_3 + 0X_4 + X_5 + 0X_6 = 120$$

$$10X_1 + 5X_2 + 4X_3 + 0X_4 + 0X_5 + X_6 = 88$$

and $Z = 30X_1 + 10X_2 + 40X_3 + 0X_4 + 0X_5 + 0X_6$

The establishment of the initial feasible program or the basic feasible solution (BFS) in which real activities at zero levels and disposal activities are equal to resource supplies is the first task of the simplex method. Profits will be zero in the basic feasible solution until real activities enter. The simplex method systematically solves the linear programming problem in such a way that the objective function changes monotonically to converge with its optimum. In the process each iterative feasible solution is checked to determine if it is the optimal solution.

Limitations

A linear programming model is not an economic model yielding estimates of real world situations but is a mathematical statement of an objective which is optimised within the stated constraints. As such, any linear programming model is limited by two main factors.

1. The researcher's ability to describe in mathematical terms all realistic constraints.
2. The resources available for developing a robust

enough model to express all possibilities which are important to the maximizing function.

Therefore a linear programming model such as the linear programming model for Northern Alberta agriculture applied to the Smoky Lake situation is not free from these limitations. The regional economic impact analysis is based on a sample survey whose observed facts cannot be taken as facts regarding the population. The problems involved in summarising accurate input/output data and deciding on relevant prices and suitable resource restrictions make the limitations very real.

The Model

The model of agricultural technology for policy analysis in Northern Alberta is an attempt to develop a regional or national model that is designed to give a full picture for policy alternatives. The model is employed in this study for the following reasons:

1. It provides a comparative analysis of agriculture resource utilization in Northern Alberta under various policy alternatives using disaggregated regional data;
2. It contains artificially imposed constraints; and
3. It is designed in such a way that more data can be added and a wide range of policy programs can be considered.

The model consists of columns, rows and the right-hand sides. The elements are listed by column order and row order. The number of elements by row order excludes the right-

hand side but includes one slack variable for each row.

The model is a single period non-stochastic linear program of one agricultural region, Northern Alberta. There are 104 activities and 98 constraints. Out of these 104 activities, there are 57 primary producing activities, and 46 exchange and accounting activities. The prices and costs for the activity rows are based on Alberta averages for 1974 and from the primary data (Appendix 7). In the 98 rows, there are 9 land constraints, 4 labour constraints, 3 cash constraints, 3 fertilizer constraints, 5 equipment constraints and 12 livestock constraints. The right-hand constraints were developed from 1971 Census figures and from assumptions on resource availability in the County of Smoky Lake. The right-hand constraints used are contained in Table 23. The matrix structure of the model is indicated in Table 24, part A., while part B shows the summary of the matrix. The identification of the letter codes used is contained in Appendix 8.

Cash flow is the objective function. It is maximized by minimizing an equation which expresses all income or receipts with negative signs and all outflows or cost expenditures with positive signs. The structure of the model is flexible and it allows the formation of various objective functions for future analyses. For example, for future analysis, one could maximize the value of production or minimize the cash expenditure.

G	GREATER THAN	1.000.000.000000	3				

Apart from various objective functions, the model includes shadow prices, dual problems and the marginal cost. The shadow prices represent the marginal value products of the corresponding resources. They indicate possible gains through acquisition of scarce resources, and they serve as a basis for computing the total value product and, therefore, as one check on computations. The dual problem is to find the value of resources such that the total value of resources is the minimum consistent with no activity having an imputed surplus. The marginal cost is the increase in total costs resulting from a one-unit increase in production. Thus, in the model, the objective function under the real activity will give the marginal cost of producing an extra unit of the activity.

Data Collection

The study region in Northern Alberta is defined as census divisions 10, 12, 13, 14 and 15. The analysis which was completed first covers census division 15. The present analysis involves pooling the data collected from Smoky Lake County, which is part of census division 12, with that for census division 15.

The data for Smoky Lake were obtained from both primary and secondary sources such as the published information on resource availability in that county. The primary data were collected through a questionnaire survey that involved a sample of 35 farmers.

Survey Design

A design is a plan for obtaining and analysing data. The procedure followed in this study began with designing a questionnaire format. The first step was to lay out a general plan to fit in with the required information. The information was aimed at providing an input-output accounting for alfalfa on the basis of a selected plot of ten acres or more. A period of three years was covered starting with the establishment of alfalfa.

When the preliminary format was finished, the questionnaire was tested on five farmers. The procedure was to visit each of the five farmers selected and record the length of time required for each interview, making sure that some of the controversial questions were avoided. For example, a question such as "How much income do you earn?" may hinder the co-operation of the farmers.

During this preliminary survey it was observed that there was difficulty in holding the farmers' attention for more than one hour, and farmers have a good reflexive recall of the various steps they use in their farming operations. It is therefore important to design a questionnaire that will lead the farmer through a chronological order of farm operations for each enterprise.

Selecting the Sample

There are many alternatives in selecting the items which will comprise a sample.¹ Three alternatives were considered in this study:

1. Simple random sample;
2. Systematic sampling; and
3. Stratification.

Simple Random Sample-- A random sample is one in which each individual in the population is equally likely to be sampled. In terms of probability this implies that the probability of any particular member being selected is $1/n$, where n denotes the number of individuals in the population. There are several ways to actually carry out the physical process of random sampling:

1. Record each person or name on a slip of paper, mix the slips well in a large container and then draw the number required thoroughly remixing after each individual drawing.
2. Assign each person a number and then draw a random sample of numbers. In other words, a random sample may be obtained by consulting a table of random numbers and reading off a pair of digits for each individual required in the sample.

The main advantage for advocating this method is that random sampling leads to probability models for distributions.

¹ E.R. Babbie, Survey Research Methods (Belmont: Wadsworth Publishing Company, Inc., 1973).

The importance of this is that conclusions to be drawn about populations through means of a sample are based upon probabilities. The major disadvantage is that the method is physically inconvenient for a large population. For this reason, it is time consuming and therefore costly.

Systematic Sampling-- If one were to draw a 10 percent sample from a list of 730 cards, one might select a random number between 1 and 10, say 4, and pick every 10th card thereafter, i.e., the cards numbered 4, 14, 24 and so on, ending with card numbered 724. A sample of this kind is known as a systematic sample since the choice of the first number, i.e., 4, determines the whole sample.

A systematic sample has the following advantages:

1. The actual selection of a systematic sample is quicker, easier and therefore less expensive than a random sample; and

2. Systematic sampling distributes the sample more evenly over the listed population.

There are two potential disadvantages in systematic sampling:

1. If the population contains a periodic type of variation, and if the interval between successive units in the systematic sample happens to coincide with a multiple of it, one may obtain a sample that is badly biased; and

2. From the results of a systematic sample there is no

reliable method of estimating the standard error of the sample mean.

Stratification--In constructing a valid sampling scheme one has no more than a reliable list of all sampling units in the population, arranged in some recognizable order. But one could use some additional information that might improve on the precision of the random sample estimates. For example, perennial crops can be classified by date of planting, dairy cows by breed. Such information can be used to arrange the units in a grouped or ordered list from which samples may be drawn. A sample of this kind is known as a stratified sample since each population is divided into groups or strata such that 'y' can be expected to be less variable within each stratum over the population as a whole.

Method Applied

The disadvantages and the advantages contained in each of the three alternatives have been noted. The choice of method to use was based on the ability to rectify the disadvantages. For example, the use of a computer can overcome the problem of physical inconvenience characteristic of a simple random sample.

A simple random sample was selected because a computer was to be used. The computer program numbers the elements in the sampling frame. Then it generates its own series of random numbers and prints out the list of elements selected.

Sample Size

The question "How large a sample ought to be taken?" is meaningless on its own according to Sampford. "A sample size appropriate to a given investigation is a compromise between accuracy needed in the results and the cost of obtaining accuracy."¹ The sample size for this study was determined after reviewing expected variance of the variables to be estimated, the cost of sampling and the time available for sampling and data manipulation. The time factor was very important. As such, a sample size of 35 was considered appropriate for the time available.

According to Snedecor: "We want to avoid making the sample so small that the estimate is too inaccurate to be useful. Equally, we want to avoid taking a sample that is more accurate than we require."² To this end, a sample size of 35 will probably give a reasonable estimate of the population mean, provided the population is distributed normally. However, the standard error could be higher than with a larger sample size. However, this study is more interested in the population mean than in the sample mean.

Listing the Population

The sampling frame was the list of all farmers in

¹ M.R. Sampford, An Introduction to Sampling Theory (Edinburgh: Oliver and Boyd, 1956), p. 206.

² G.W. Snedecor, Statistical Methods, (Ames: The Iowa State College Press, 1957), p. 501.

Smoky Lake County as obtained from the District Agriculture Office in Smoky Lake. The list was an updated version of the 1973 list as amended by the District Agriculture. The sampling frame contained 779 names from which 40 were selected at random (to provide up to five replacements). The first 35 names constituted the sample. Replacements were used if an interview could not be satisfactorily completed.

The survey was conducted during the last two weeks of August, 1974. The procedure was to call the selected farmer by telephone to explain the need for the survey and to request an interview. In most cases, the meeting followed soon after the telephone conversation. One farmer became hostile when he was visited and was therefore replaced in the sample. This was the only replacement and the survey was completed without any serious problems.

Tabulations and Statistical Analysis

The data collected from the questionnaire survey were compiled for expression in terms of linear programming units. As already stated, the questionnaire format was designed to lead the farmer through a chronological order of farm operations. For example, field operations involved first ploughing, second ploughing, harrowing, seeding, spraying and harvesting (a sample questionnaire is included in the appendices). The time expended on these field operations was recorded in terms of total tractor hours and total man hours. Then the information was transformed into man hours per acre and tractor hours per

acre. The same manipulations were done for production expenses such as fertilizer and seed, and return per acre was then calculated.

Further transformations involved the manipulation of the tractor variable cost per acre. This was made possible by the information on tractor variable costs per hour obtained from Farm Machinery Costs issued by the Alberta Department of Agriculture. All the transformations performed from the establishment of alfalfa to the end of three years are contained in the appendices. After transforming data into these units, a statistical analysis was carried out.

The statistical analysis involved the estimation of population parameters such as the mean, standard error, standard deviation and the coefficient of variation. Then tests of significance were done. Tables 25, 26, and 27 show the population parameters, and Tables 28, 29 and 30 show the results of the t-test for kurtosis and skewness on technical coefficients.

The estimation of population parameters serves two purposes: One is concerned with determining whether the estimate is biased and the second is concerned with determining the precision of an estimate. For example, the mean for pounds of nitrogen applied per acre may be of a questionable value. From data compiled, it was found that out of 35 farmers interviewed, only 4 applied fertilizer on establishing alfalfa. It is not surprising that the results of the t-test for kurtosis

* t - calculated > t - distribution to an infinite number of degrees of freedom at 2.5 percent level.

and skewness shows a positive level of significance for nitrogen application. A level of significance for positive skewness indicates an excess in the number of items smaller than the mean. Figure 1 is a histogram showing an example of positive skewness for a frequency distribution of alfalfa acres.

Variability

Variability means the degree to which numerical data tend to spread about an average value. Variability in the size of coefficients of the model in this study may be related to the causes of variation in general.

- a) Variation may be due to errors of observation or measurement.
- b) Variation may result from rounding figures.
- c) Variation may be caused by the restrictions imposed.
- d) It is characteristic of large things to vary greatly and small things to vary little.

There is, therefore, an ever present variation, and according to Snedecor: "The facts observed in a sample cannot be taken as facts about the population. Our job then is to reach appropriate conclusions about the population despite sampling variation."¹

The model is a set of average farm enterprises with probably higher associated variance than would have been the case if the enterprises had been better refined. The result

¹ Snedecor, Ibid. pp. 1-2

Figure 7

A HISTOGRAM OF THE FREQUENCY DISTRIBUTION OF ALFALFA ACRES,
SMOKY LAKE COUNTY, 1974

is not as restrictive as may appear on the surface for associated with each coefficient is a measure of the standard deviation, and associated with each enterprise is a definition of the assumptions surrounding that enterprise. For example, referring to cow-calf enterprises, according to Apedaile:

It would be possible to define three cow-calf enterprises based on the average cow-calf enterprise. The first is the average enterprise and the second and third are derived using the average plus or minus one standard deviation for all coefficients. Since all coefficients do not have the same coefficients of variation, one can expect three different cow-calf enterprises. Variations on this average cow-calf enterprise are possible by adding or subtracting standard deviation to or from the mean coefficients in the base enterprise.¹

Interpretation of Results

Table 31 indicates the results for the slack activities in the optimum solution. The first column, headed "Number", gives the internal identification of vectors. The second column, headed "Row", identifies the row code as listed in Appendix 7. The third column is headed "AT" and gives the solution according to the following code:

BS ... in the basis and feasible,
 FR ... nonbasis, free,
 EQ ... nonbasis, artificial or fixed,
 UL ... nonbasis, activity at upper limit,
 LL ... nonbasis, activity at lower limit.

The fourth column is headed "Activity". This indicates the

amount of resource used or required. The fifth column is headed "Slack Activity" and indicates the amount of resource unused, or the requirement overfulfilled if the row has one sign throughout. The sixth column is headed "Lower Limit". This is the lower limit for a "greater than" requirement or equality constraint. The seventh column is headed "Upper Limit" and indicates the limit of resources available for a "less than" or equality constraint. The eighth column is headed "Dual Activity" and is the shadow price or marginal value product associated with a one unit reduction in resource availability.

The results (Table 31) indicate that stubble and fallow land of classes 1, 2 and 3 is limiting at upper boundaries except stubble land on soil class 4. The same situation holds for natural pasture and improved pasture. On the other hand, labour use is in excess supply, indicated by the presence of very large amounts of slack activity in the labour constraints. As a result, labour use has a shadow price of zero. The same interpretation is extended to the equipment constraints.

Table 32 indicates the results for the column activities in the optimal solution and has a format similar to the row section. The first column is an internal identification. The second column, headed "Column" is the coded identification. The third column, "AT" identifies the status of activities in the solution and uses the same status codes as those in the "Row" section. The fourth column, "Activity", is the level at

which that activity enters the solution, and is expressed in the same units as the input data. The fifth column, "Input Cost", gives the value of that activity in the objective function. Columns six and seven give the "Lower Limit" and "Upper Limit" for each activity. The eighth column, "Reduced Cost", is the change in the value of the objective function for activities not in the optimal solution that would result if one unit of the activity were forced into the solution. Alternatively, it may be considered the amount of change required in the objective function to bring the activity into the optimal solution.

The activity levels (Table 32) show alfalfa, barley, oats, fallow and rape as the only cropping activities. These activities are tied mainly to the relative selling price and to the coefficients generated to simulate cost of production and yields. Given the selling prices used in the model, the results are realistic, but if the selling price were reduced or increased for the other cropping activities, the results could change considerably. For example, wheat is not in the solution and under the reduced cost column, we find that forcing wheat activity on stubble land of class 3 would decrease the value of the objective function by \$45.83 for each acre of wheat.

Table 33 shows rows at limit level. The first five columns are the same as for Table 31. The sixth column shows the "Lower Constraint Limit" (lower limit) and "Upper Constraint Limit"

(upper limit) for each row. The seventh column, "Lower Activity", gives the lower limit to which resources may be decreased at a reduction in profit per unit, given by the corresponding "Unit Cost" of column eight. Below this limit, the change in gross farm income per unit of resource (shadow price) will change. The tenth column shows the "Limiting Process" which identifies the row or column that would change if the limits of change shown under lower activity or upper activity are exceeded. Column eleven, "AT", shows the status of the limiting process column or row if the lower activity or upper activity limits of change are exceeded.

Table 34 shows columns at limit level. "Lower Limit" in column six is the specific lower limit, and where no limit is specified, an implied limit of zero is assumed. "Upper Limit", again in column six, is the upper limit for the activity. The ninth column, "Upper Cost", shows the highest cost for inputs or lowest price for output that will permit the activity to be maintained at its present level and status in the optimal solution. "Lower Cost" is the lowest cost or highest price that will permit the activity to maintain its present level status in the optimal solution.

Tables 35 and 36 show the rows and columns at intermediate level. These are interpreted in the same way as the rows and columns at limit level. The significance of these rows and columns at intermediate level is that they provide a comparison between upper and lower limit activities within a range of prices. The reasons for these limiting activities may not always

be explained from viewing the model. However, the tables show the sensitivity of the program to price and resource changes. As an example, in Table 35, the available time of middle tractors is part of the base solution (BS) at 148,001 hours. There are 755,998 hours of slack activity or nonuse. Column six shows the lower limit of zero and an upper limit of 904,000 hours. Going on to columns seven, eight and ten, the availability of middle tractors could range from 148,001 hours to 164,407 hours, and a per unit cost of \$2.89 to \$12.44 without affecting the base solution. If the available time of middle tractors were to move beyond the lower activity, the establishment of alfalfa for the plant could be affected, and if there was a move beyond the upper activity, it would affect a change in wheat production on fallow land of classes 1 and 2.

Comparative Simulations

The comparison of farming patterns with and without the plant was based on the following assumptions:

1. The number of cattle was not allowed to decline by more than a net cull rate on the premise that producers would not likely abandon cattle as a hedge against crop risk and major uses of nonarable land.

2. Alfalfa is produced on stubble land of soil class 3 in competition with the major cereals and greenfeed.

3. Alfalfa can either be marketed as hay or as a supply to the dehydration plant.

The analytical procedure involved changing the price paid in each alternative market. By this process, relative prices for each market were established at \$49.82 per ton for alfalfa hay and \$36.17 per ton for the plant. A ceteris paribus increase over the relative price for either case resulted in diverting the alfalfa to one or the other of the respective markets. These relative prices are in the neighbourhood of farmer paid prices and the price used in cash flows projections.

Examination of the results (Table 37) shows that the presence of the dehydration plant would not be expected to change the cropping and livestock patterns in Smoky Lake County. The acreage for the individual crop included in the production with the plant is the same without plant. Wheat and hogs are primary activities not included in either case and mixed hay and rape account for the highest acreage, 78,471 acres and 73,549 acres, respectively, using over 60 percent of the available land. Although the results are in contradiction to what is going on in the County, it should be remembered that Linear programming is approximation of reality. It does not represent any external economies and diminishing returns to scale. In addition, 1974 experienced unusually high prices but farmers do take time to adjust. Therefore, Linear programming only indicates the direction to which to adjust.

The assumption regarding livestock was relaxed. As a result, the livestock activity was excluded from the objective

TABLE 37

COMPARATIVE SIMULATIONS OF CROPPING AND LIVESTOCK
PATTERNS IN SMOKY LAKE COUNTY WITH AND WITHOUT AN
ALFALFA DEHYDRATION PLANT, 1974

Enterprises	Units	\$/CWT	With Plant	Without Plant
Barley	acres	109.58	64	64
Oats	acres	87.65	40,796	40,796
Rape	acres	282.50	73,549	73,549
Fallow	acres	N.A.	12,327	12,327

Alfalfa Production	acres	37.17 ¹	9,428	nil
Alfalfa Hay	acres	36.00 ¹	nil	9,428
Mixed Hay	acres	N.A.	78,471	78,471
Improved Pasture	acres	N.A.	22,121	22,121
Wintering Cows	cows	N.A. ²	23,062	23,062
Summering Cows	cows	N.A. ²	21,468	21,468
Hogs	sows	43.50 ³	nil	nil

¹ The price for alfalfa hay is \$50/ton. The quoted prices (\$36.17 and \$36.00 per ton) are competitive prices for plant harvested alfalfa on a sun cured hay basis.

² The prices are not quoted due to the variety of outlets for product.

³ The price of \$43.50 is or market hogs.

function. But the exclusion of livestock from the activities increased the production of alfalfa from 1,886 acres to 8,737 acres, almost four times the original objective.

Comparison was made of resource use and agricultural enterprises in Smoky Lake County (Table 38). The results show that the presence of the plant decreased the value of agricultural production from \$13,038,959 to \$12,987,514. At the same time, the presence of the plant reduced operating costs, resulting in a higher net farm income (\$3,304,912) than without plant (\$3,100,894). The plant has also reduced the labour requirements thus increasing the problem of underemployment from 69 percent to 70 percent.

Total Labour Unused	Hours	2,198,368	2,180,718
Underemployment	Percent	70%	69%

CHAPTER V

SUMMARY AND CONCLUSIONS

Summary

This study attempted to do four things:

1. To examine the financial viability of Smoky Lake Alfalfa Processing Plant.
2. To examine the competitive impact of alfalfa production on other farm enterprises.
3. To examine the regional impact of the plant as a market outlet for local resource-based production.
4. To examine policy recommendations for the future of the plant.

The procedures followed in this study were:

1. To define alfalfa processing as related to the primary agriculture concept and to examine the recent expansion of alfalfa dehydration in the province of Alberta.
2. To investigate the alfalfa industry in Alberta in terms of production, processing and markets for alfalfa products. The main area of this study was Smoky Lake County and, in general, the Alberta perspective.

3. To review literature on the concept of cash flow.

The concept of cash flow was defined and the areas where cash flow analysis is applicable were identified. The importance of discounting cash flows was emphasised and alternative measures of financial viability examined. A detailed documentation of

how the cash flows projections for Smoky Lake Alfalfa Processing Plant were derived formed the basis of the analysis. The sensitivity analysis provided a check on the estimated projections by varying the price paid for the final product and throughput percent of capacity.

4. To review literature on the theory of linear programming. The formulation and solution of linear programming problems were attempted. A linear programming model for Northern Alberta was applied in the analysis. The model was described with emphasis on size and density. The column activity prices and cost figures and the right-hand side constraints for Smoky Lake County were listed.

The sources of data were outlined, especially data collected through farm questionnaires. The single-stage sampling and the actual survey were explained.

The data obtained were converted to standard units for inclusion in the linear programming model. The objective was to maximize cash flow by minimizing an equation which expresses all production in negative numbers and all input coefficients in positive numbers.

Conclusions

The results of the cash flows projections show that the Smoky Lake Alfalfa Processing Plant is financially viable under defined assumptions. The net present value and the financial rate of return indicate that the plant is capable of

paying a higher rate of interest than that charged in the market place and still recover the capital invested into it. The assumed price in the analysis is lower than that currently obtained on the market. This ensures overestimation of revenue. On the other hand, the assumption made for the level of throughput is about 25 percent higher than the current one. It would appear that if the assumed capacity level of throughput were not achieved, the results could be lower than expected.

The phasing of capital outflows needs mention. To project debt service outflows, no future long term borrowing was taken into account. If a substantial amount of money is borrowed in the future, the expected financial position of the plant might be affected.

The study attempted to test what happens to the financial viability of the plant if the assumptions made for price and capacity were different from the actual results. The results of sensitivity analysis indicated that the most likely assumption on price is realistic and that the plant is viable at a lower throughput percent of capacity than that projected. On the other hand, at a price lower than \$60 per ton of pellets, the financial rate of return of the plant is less than the opportunity cost of capital, even at full capacity of throughput. Therefore, all things being equal, the selling price and throughput are identified as the most important variables responsible for the financial viability of the plant.

The analysis of the competitive impact of alfalfa production and the regional economic impact of the dehydration plant on farming enterprises were also attempted. The results of the activity levels showed rape, oats, alfalfa and barley as the only cropping activities. The results indicate that rape is the most important crop activity followed by (in the order of importance) oats, alfalfa, and barley. Wheat production was not competitive with the other cropping activities. These activities are tied closely to the relative selling prices and the 1974 commodity prices greatly favoured rape production. The sensitivity analysis indeed identified the wheat sale activity and the relatively low price attached thereto as limiting production of wheat. Given the current price paid for the various crops, a higher proportion of the available land should be allocated to rape production rather than to barley, oats, alfalfa or wheat. It can also be concluded that since alfalfa ranks third in importance at given prices, its production for processing purposes would not have a significant impact on the cropping and livestock patterns in the county. Alfalfa is not as much a competitive as a supplementary enterprise within the given soil classification.

The comparative simulations indicate that no change in the cropping and livestock patterns would be expected since the establishment of the dehydration plant. It is therefore concluded that the plant is not likely to have regional impact on

resource allocation except to slightly shift the demand for labour off farms and into the part time market. This conclusion is supported by the fact that as few as 30 farmers market their alfalfa through the plant, many of them for labour saving reasons. The president of the plant was of the opinion that farmers involved are capable of doubling their supply. This is an indication that there is potential impact for increased production of alfalfa and the location of the plant in Smoky Lake is justifiable.

The plant also has very few openings for wage employment. At the peak periods such as the first cut of alfalfa, a total of 35 farmers are employed. Most of these employed, as many as 28 men, are involved in field operations. Another indication is that those who market their alfalfa through the plant and those employed at the plant are centered in and around Smoky Lake town where the plant is located. It would perhaps be more meaningful to speak of local rather than regional impact because of the limited scope in which the influence of the plant is felt.

By comparative simulations it was possible to establish 'trigger prices' for unprocessed alfalfa below which alfalfa production is not profitable. The trigger price in this analysis is \$36.17 per ton of suncured hay equivalent or about \$12.00 per ton on a fresh cut basis assuming a 3:1 conversion ratio. This price is in the neighbourhood of farmer paid prices

established in recent years by the plant. Therefore there seems to be little room for reducing this price to improve the cash flow of the plant. Given the marked shortfall in deliveries of fresh alfalfa to the plant, this price may be insufficient as an incentive to produce, and may actually discourage efforts and expense to improve the low yields.

Recommendations

(1) Throughput and price have been identified as the most important variables for improving the cash flows of the plant. But the plant cannot control the price at which to sell. It is therefore recommended that throughput should be increased if losses have to be avoided. It has been suggested¹ that a major improvement in the efficiency of the alfalfa processing industry could be achieved by extending the length of time during which plant facilities are in operation each year. Related to this is the fact that frequent mechanical problems can interfere with the available time for operation; therefore, it is important to employ a well-trained mechanic.

2. Another recommendation is that future expansion of the plant facilities should be planned and executed, only after the present facilities have been utilized to full capacity. A historical throughput of capacity ratios shows that the plant has been operating at slightly less than half capacity. It would

¹ Alberta Department of Agriculture, op. cit.

therefore be unrealistic and costly if more funds were committed to creating extra facilities.

3. Short term borrowing from commercial banks should not be encouraged. Short term borrowing can be costly and should not be resorted to unless absolutely necessary. Related to short term borrowing is the fact that management is currently negotiating for a long term loan. The amount sought should be related to the expected throughput and price. Only after making sure that the loan will add more to benefits than to costs can such borrowing be justified.

4. A policy recommendation is that if the plant has no significant impact on the local economy, incentive loans and loan forgiveness should not be extended to the plant. But the plant has the potential to add to income without outcompeting other enterprises and as such the plant merits assistance. In fact it would seem that the plant is promoting² farm adjustments since it is the old who are very much involved in growing alfalfa in the county.

WHT 3S	Wheat production-land class 3,stubble
WHT 4F	Wheat production-land class 4,fallow
WHT 4S	Wheat production-land class 4,stubble
WHT-IN	Wheat inventory
WHT-SD	Wheat seed transfer
WHT-SL	Wheat sold
WHT-SP	Wheat seed purchase

Appendix 9

Survey Questionnaire

Local Impact of Alfalfa and costs of ProductionCoded Values

1. Location: Section ____ Township ____ Range ____	_____
2. Years of formal education: Man ____ Wife ____	_____
3. Year started farming 19 ____	_____
4. Year started farming on this land ____	_____
5. Number of family members between the age of:	
Under 15 years _____	
15 -- 24 years _____	
25 -- 34 years _____	
35 -- 44 years _____	
45 -- 54 years _____	
55 -- 64 years _____	
65 -- 69 years _____	
over 70 years _____	
6. Total area of land _____ acres	_____
7. (a) Area owned _____ acres	_____
(b) Area rented (leased) _____ acres	_____
(c) Area rented out to others _____ acres	_____
8. Total area of cultivated land _____ acres	_____
(a) Area under summer fallow _____ acres	_____
(b) Area under crops _____ acres	_____
(c) Area of improved pasture _____ acres	_____
9. Area of unimproved native pasture _____ acres	_____
10. Area of bush and unused land _____ acres	_____
11. Area of new breaking _____ acres (1973/74) _____	
12. Crop(s) planted in the area of new breaking _____	

Crop and Livestock History

1. Acreages and yields for three years

Crop	1972		1973		1974	
	Acres	Yields	Acres	Yields	Acres	Yields
Wheat						
Barley						
Oats						
Summer fallow						
Mixed grains						
Rye						
Flaxseed						
Rapeseed						
Alfalfa						
Alfalfa mixtures						
Other tame hay						
Other crops						

2. Livestock Patterns:

	1971	1972	1973	1974
No. of beef cattle				
No. of beef cows				
No. of dairy cattle				
No. of dairy cows				
Number of sows				
Other				

Input/Output accounting for Alfalfa (on the basis of a selected 2 to 5 year old plot 10 acres or more in size)

Coded Values

First Year - Establishment and Maintenance:

1. Year planted 19 _____
2. Number of acres _____
3. Previous land use (fallow, grain etc.) _____
4. Type of mixture _____
5. Type of cover crop _____

Field operations	no. of men	man hours	tract. hours	tract. make	h.p.	age	
6. 1st cultivation							
7. 2nd cultivation							
8. Harrowing							
9. Seeding							
10. Spraying							
11. Harvest of cover crop							
a) swathing							
b) combine							
c) baling							
d) raking							
e) transport & storage							
12. Other operations							

total tractor
hours _____

35. Spray							
36. Twine							
37. Hired labour							
38. Other inputs 1 _____							
2 _____							
3 _____							

Harvested Alfalfa	tons	price
39. Yield of Alfalfa.		
40. Use of harvested alfalfa		
a. Use on farm		
b. Sold to another farmer or dealer		
c. Delivered to dehydration plant		
41. <u>Background Information:</u>		
1. How many acres were seeded to alfalfa in 1974?		
2. Do you intend to expand alfalfa in 1975?		
3. How do you determine the price at which to sell?		
4. Are you satisfied with the present pricing system?		
5. Do you prefer contract arrangements for your alfalfa?		
6. What kind of contract arrangements do you prefer?		
7. What problems do you usually experience as an alfalfa grower?		
8. In your opinion has there been a shift to more alfalfa in neighbouring farms since the plant started?		

Coded
Values

9. If there is a shift, is it in addition to previous enterprises
or is alfalfa replacing some crops or livestock?
10. What changes on your farm could you say have been made because
of your alfalfa production over the last five years?
